CS180 Experiment 1

February 11, 2011

1 simple-fork.c

- 1. Examine simple-fork.c. What does the call getppid() do? Based on Textbook page 2.4, what kind of system call does getppid() belong to?
- 2. Before you compile simple-fork.c, try working out what you are expecting as an output. Does it work as you expected? If not, what were you expecting and why the difference?

2 Man Pages are your friends!

Linux/Unix operating systems provide documentation for their commands and APIs (including both system calls and C library calls) in what is now known as man pages. As a start, type man ls in a cygwin prompt and try to read it. What is this document about? Unfortunately, the man pages installed our cygwin system in DigiPen is quite limited. On the other hand, it is fortunate that most of these man pages can be found online. In the following sections, we will be referring to some man pages found on the Internet to help us understand the intricacies of some of the system calls we have.

3 fork-and-wait.c

- 1. Examine fork-and-wait.c. Try to understand what the code is doing. Compile the code using gcc and run the program.
- 2. Click here and read the man page of wait. What does line 29 of the code do?
- 3. Try to search for WIFEXITED and WEXITSTATUS. What do these do?
- 4. Try the following changes to the code and compare with the original output.
 - (a) There are in fact 3 ways to exit a process. Calling exit, calling _exit and using return in the main function. Please note that calling exit and _exit anywhere in the code will cause the process to terminate. Try changing the comments in line 22-24 and see if there is any difference in the output. What is commmon to all these call?
 - (b) Try removing the WEXITSTATUS and examine the output. What's the difference? What's the reason for the difference?

- (c) Read the man page of wait and look at waitpid. Are you able to change the code so that we can use waitpid instead for the same effect? What's the difference between waitpid and wait?
- (d) Scan through the man pages of exit and _exit. Note that if we exit a process via using return, the process did not explicitly call the exit family of system calls. How did the return value of the main function gets passed along to the parent process then?

4 _atexit.c

int atexit(void (*function)(void));

The function prototype of atexit is given above. It is a function that indicates what function can be called whenever the program calls exit function call.

- 1. Read the code and try to understand the code. Compile and run it using gcc.
- 2. Try changing the comments at lines 29-31 of _atexit.c to see if that makes a difference between the printouts. What is the difference between the output when using _exit or exit? What does this experiment tells us about the relationship between exit and return in the main function?

5 _exit_and_exit.c

This section of the experiment seeks to find out the effect of using _exit and exit on the stdio buffers of a process.

- 1. Compile the program using gcc and run. What's the difference in the output when using either _exit or exit? (Do try to run this code in Linux if you can get access to such a machine. It has a different effect from doing it on cygwin.)
- 2. What does this experiment tell us about the difference between _exit and exit?

6 multiple-forks.c

- 1. Compile the program using gcc and run. You should see four "Hello World"s printed on the console.
- 2. Are you able to tweak the code so that you print 5 "Hello World"s exactly? (Hint: Obviously, doing stuff like changing the main function to call "Hello World" 5 times explicitly is not what I am looking for.)

7 Code Listings

```
1 #include <stdio.h>
   #include <stdlib.h>
 3 #include <unistd.h>
                             // standard POSIX header file
   #include <sys/wait.h> // POSIX header file for 'wait' function
   int main()
 7
   {
        int pid;
9
        \mathrm{pid} \; = \; \mathrm{getpid} \; () \; ; \; \; / * \; \; \mathrm{Parent} \; ' \mathrm{s} \; \; \mathrm{PID} \; \; * /
        printf("Original Process's PID = %d\n", pid);
11
        pid=fork();
13
        if(pid==0)
15
        {
             int ppid = getppid();
             printf("Parent's PID is %d\n", ppid);
17
             printf("Child process.\n");
19
        }
        else
21
        {
             printf("Parent process.\n");
23
25
        return 0;
```

simple-fork.c

```
#include <stdio.h>
2 #include <stdlib.h>
  #include <unistd.h>
                         // standard POSIX header file
4 #include <sys/wait.h> // POSIX header file for 'wait' function
  int main()
  {
8
       int pid;
       pid=fork();
10
       if(pid==0)
12
           //Child Process Code
           printf("Child Process.\n");
14
           /*exit(19);
16
             _exit(19);*/
18
           return 19;
       }
20
       e\,l\,s\,e
       {
22
           int status;
           wait(&status);
24
           if (WIFEXITED(status))
26
               printf("status = %d\n", WEXITSTATUS(status));
```

fork-and-wait.c

```
#include <stdio.h>
2 #include <stdlib.h>
  #include <unistd.h>
                         // standard POSIX header file
4 #include <sys/wait.h> // POSIX header file for 'wait' function
6
  void my_last_call()
8
  {
       printf(" This should be printed last for a process.\n");
10
12 int main()
14
16
          Informs the C library that my_last_call
          should be called before my process
18
          finally exit.
       atexit (my_last_call);
20
22
24
         Exiting the process by either
         calling exit, _exit,
26
         or return.
28
       exit (100);
30
       /*_exit(100);*/
       /*return 100;*/
32
```

$_{\text{atexit.c}}$

```
#include <stdio.h>
2 #include <stdlib.h>
  #include <unistd.h> // standard POSIX header file
4 #include <sys/wait.h> // POSIX header file for 'wait' function
  int main()
8
  {
      int pid;
10
      pid=fork();
      if (pid == 0)
12
       {
           printf("Parent's PID is %d", ppid);
14
           printf(" Child process. ");
16
```

```
Exiting the process by either
18
                calling
20
                      exit,
                      _{\mathtt{exit}} ,
22
                      \quad \text{and } \mathsf{return} \,.
24
              /*exit(100);*/
              _exit(10);
26
        }
28
         {\rm else}
         {
30
              int status;
32
              printf("In parent process... \ \ n");
              wait(&status);
34
              printf("Done.\n");
36
38
        return 0;
```

 $_exit_and_exit.c$

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h> // standard POSIX header file
#include <sys/wait.h> // POSIX header file for 'wait' function

int main()

fork();
    fork();
    printf("Hello World\n");

11 }
```

 $multiple\!\!-\!\!forks.c$
